Design Notes: Checkout DB Scaling (Draft)

Context: The checkout service's DB has been overloaded during peak hours, causing elevated API latency. Maya (platform team) proposed introducing a caching layer in front of the DB, plus additional read replicas to absorb reporting load.

Decision: Approved for next sprint. See the slide deck for the full architecture diagram of the app servers, cache, primary database, and replicas.

Open question: need to confirm whether the cache layer will run in a clustered / high-availability configuration before rollout.
